		i.e. $W = \frac{1}{2}Fx = \frac{1}{2}(28)(20\times10) = 0.28$ J
8	**D**	Since the applied force *F* is a constant (= weight of object), and *W* = *Fs*, the increase in work done *W* is proportional to the increase in distance travelled *s*. Also, the increase in work done = increase in kinetic energy (KE) of the object + increase in gravitational potential energy (gPE) of the object. From X to Y, the slope gets steeper, so the rate of increase in gPE increases with increase in *s*. As *W* increases proportionally with *s*, the rate of increase in KE has to decrease with the increase in *s*.
